In the present study, we examined the efficacy of the combined use of human pancreatic juice (h-pancreas) and the protease inhibitor nafamostat mesilate (NM) in the prevention of acute pancreatitis in patients with acute pancreatitis. Fifty-two patients with acute pancreatitis were randomly assigned to one of two treatment groups: Group H, patients who underwent transpapillary drainage of the pancreatic duct after artificial sphincter placement (n = 25) or Group H+P, patients who underwent the same procedure after transpapillary drainage of the pancreatic duct and pancreatic juice collection (n = 27). To prevent the activation of trypsinogen by artificial sphincter placement, the other 25 patients with acute pancreatitis who did not undergo transpapillary drainage of the pancreatic duct and pancreatic juice collection served as the control group (Group N). The duration of pancreatitis was significantly shorter in Group H than in Group N (median, 21.0 vs. 32.0 days, P = 0.0044). No significant difference was observed between Group H and Group H+P. The duration of pancreatitis was significantly shorter in Group H than in Group N, regardless of treatment with h-pancreas or NM 82157476af
